

General Info

- Hosting is on GitHub Pages ([repository link](#))
- Database managed by Supabase
- All written in HTML, Bootstrap CSS, and Vanilla JS

Hey Aditya!

We're planning to rebuild the website from the ground up and wanted to share a few areas we've identified for improvement:

- **Website security:** This is especially important. Sensitive info, like `original_email` or phone, etc. should only be available to the user when they are logged in. The spam email you got was most likely from someone accessing `original_email` with the public key. Fix whatever security improvements need to be made in Supabase.
- **Loading speed:** Performance seems inconsistent. For some users it's fast, while for others it can take up to a minute. A speed test gave the site a really low score.
- **Language/framework:** The current site is written entirely in vanilla JS, but we'd like you to rebuild the components using React (or whichever libraries you think would work best).
- **Code efficiency:** A lot of this project was vibe-coded, so while it works, the code isn't as clean or optimized as it could be.
 - For example, the pagination code is hard-coded in for each page (bills, directory, blogs).
- **Database setup:** I'm not super experienced with Supabase, so some of the RLS policies are probably off. Feel free to modify or optimize them — we'll add you as a collaborator.
- **User authentication:** The current system is very simple and not secure enough. Ideally, we'd like each user to be created by us with a temporary passcode that they can change on the site. Right now, we have to manually add the user, run an external `node.js` script to sync it with auth, generate a temporary code, and then email them. If that entire process could be automated by just adding an entry to the members table, that'd be perfect.
- **General optimizations:** If you notice any functionality that could be improved, feel free to take initiative! For example, our Directory page filtering system is completely custom-coded, but I'm sure there's a better library-based approach.
- **Responsiveness:** The layout distorts on certain screen sizes. It'd be great to make sure the design looks consistent on mobile, tablet, and desktop. Example below:

In general, we'd like to keep the styling as consistent with what we have right now (general Bootstrap layout). But if you think there are any possible layout changes that may look cleaner, feel free to suggest them!

To start, we'd love for you to rebuild the **Bills** page first (with React). The functionality itself should remain pretty much the same, but we'd like to integrate your PDF reader whenever the user presses "Download Proposal." Further, it would be great to have the search filtering also account for keywords, which would be auto-created from the text extracted from the PDF. If you have any ideas for changing the layout of the individual bill cards, please pitch them. Let me know if you have any questions!

Thanks,
Ben
